Summary

The Chemical and Material Library (CML) is an extensive online catalog of substances that identifies key health and environmental hazard information and process chemistry for chemicals, polymers, metals and other materials, plus extinction threat information about tree and plant species. The CML was developed by the Healthy Building Network to support its Pharos building product selection system but is designed to be a comprehensive resource that may be used on a standalone basis to evaluate chemicals, woods and other materials in products of any type.

The CML is designed for use by a wide range of users from green building design and construction professionals, to product formulators, to policy makers and researchers. This library of over 34,000 chemicals, polymers, metals, wood species and other substances are cataloged against:

- 41 authoritative chemical hazard lists for human and environmental health concerns,
- 5 endangered wood species lists and
- 14 restricted substance lists

The CML provides a quick review of how a substance has been characterized by these 60 lists indicating the health endpoints identified, such as cancer or reproductive toxicity, and color coded level of hazard using the benchmark system of the GreenScreen™ for Safer Chemicals. The CML further describes and provides direct links to these lists, all of which have been developed by state, national and international governmental agencies and other reputable, science-based non-governmental organizations. The CML includes all lists required for product disclosure by the Health Product Declaration (HPD) and for use of the GreenScreen List Translator.

The CML addresses the following issues:

- **Direct health hazards**: Pharos screens chemicals and other materials by CAS number against authoritative hazard lists to identify hazards they may present to human health or to ecosystems directly exposed to the material.
- **Life cycle health hazards**: The Pharos team researches key materials to identify additional chemicals used, created and emitted throughout the material’s life cycle. These chemicals are then screened to identify potential health hazards to the workers and local communities near where the raw materials are mined or grown and then manufactured into products. Pharos staff conducts a preliminary literature review of life cycle chemicals for most ingredients of Pharos listed products and more in-depth research on select common ingredients
- **Endangered species**: Pharos screens forestry products and other biobased materials against authoritative lists that identify trees and other timber plant species that are directly endangered or are frequently harvested from threatened forest habitats.
- **Regulatory or voluntary restrictions**: Pharos screens chemicals and other materials by CAS number against a set of restricted substance lists which identify chemicals that may be subject to governmental regulation or avoidance policies of companies and nonprofits.

The CML is an evolving tool. Many of the approximately 80,000 chemicals in commerce have not yet been thoroughly tested for their direct health impacts and our research on the life cycle associations for each material is an ongoing project. Nonetheless, over 13,000 of the substances in the Pharos Project Chemical and Material Library have been associated with hazard information from the authoritative hazard lists, making the CML the most powerful tool available to help specifiers and formulators alike avoid identified potential hazards in materials in use and in their life cycle. We welcome your data submissions and suggestions.

Chemical Hazard

Hazard identification and restricted substance lists*

Contrary to popular belief, there is no comprehensive governmental testing program that assures that chemicals are “safe” before they are allowed on the market. The vast majority of chemicals have not been fully tested for human health impacts, and the process of identifying unacceptable chemical risks and restricting or banning use is so arduous that it has rarely succeeded.

Despite this lack of a comprehensive program, scientists have used modeling, epidemiology, and human and animal testing to identify associations between thousands of chemicals, metals and other substances and significant hazards for the environment and for the health of humans exposed to them. Lists generated from this work provide important early warnings of danger to human health and the environment, and also important market signals to specifiers, owners and product manufacturers who want to get ahead of the curve before the next chemical scandal makes news. Attention to these lists, for example, would have signaled mounting concern and evidence about a range of chemicals used in building materials, including flame retardants, stain repellents and vinyl softeners, long before the US EPA ultimately announced in December of 2009 that they would subject certain “Chemicals of Concern” to new regulatory scrutiny.†

There are two main types of lists associated with chemical hazards in the CML: chemical hazard lists and restricted substance lists (RSLs). A variety of state, national and international governmental bodies and non-governmental organizations (NGOs) maintain authoritative chemical hazard lists. These are lists of substances for which an authoritative body of scientists has undertaken a systematic review of scientific evidence and categorized the substances as having an association with a specific health or environmental hazard. There are lists for persistent bioaccumulative toxicants (PBTs) and chemicals associated with specific human health endpoints, such as carcinogens, mutagens, reproductive toxicants. This category of lists also includes lists specific to aquatic toxicants, ozone depletors, global warming gases and chemicals associated with other specific environmental impacts. Sometimes the lists will also categorize the strength of scientific evidence and certainty of the hazard (e.g., differentiating whether a substance is a “known” or “suspected” carcinogen) or the potency of a toxicant indicating the level of hazard.

In addition to lists that simply identify and categorize hazards based upon a specific health endpoint or environmental impact, there are also restricted substance lists (RSLs) which are primarily policy tools for governments, non profits or companies. RSLs frequently take into account multiple endpoints and may be based upon other authoritative hazard listings and precautionary assessments of the scientific literature. An example of a governmental RSL is the European Commission’s Directive on the Restriction Of the use of certain Hazardous Substances (ROHS) which controls the use of heavy metals in electronics. An example of a non-profit RSL is the Red List of chemicals that must be excluded from Living Building Challenge projects.‡

Looking ahead, EU countries implementing a law known as REACH have begun the long process of gathering more information about chemicals in use. Still, the majority of chemicals in use remain very minimally evaluated and regulated, if at all. In the US, efforts are underway to overhaul the governing US federal law, the Toxics Substances Control Act (TSCA), to provide the US Environmental Protection Agency (US EPA) with more tools to obtain information about chemical health hazard and regulate their use. However, it is expected that it will be many years yet before such legislation can be passed and implemented.

---

* This section describes the use of lists in the CML that address human and environmental health hazards. For information on the endangered wood species listings, refer to the Endangered Species section below.
† See Signal Blog “EPA’s “Chemicals of Concern” In Green Building Products” and CML Chemicals of Concern Action Plan list for more on the EPA announcement.
‡ View the Living Building Challenge Red List in the Pharos CML for a full description of the list and how it is applied.
Assessing substances using the CML

The CML makes the disparate information from a wide range of hazard lists available in a comprehensive user-friendly format by:

- Compiling into one searchable database the most significant published hazard lists and
- Prioritizing these lists to provide guidance for product screening to avoid the most hazardous substances.

The CML draws from governmental hazard lists such as the US EPA’s lists of PBTs and the World Health Organization’s Cancer Monographs. It also draws from non governmental organizations’ work such as Association of Occupational and Environmental Clinics list of asthmagens. All lists required for assessing chemical hazard under the GreenScreen for Safer Chemicals* are included in the Pharos CML. All lists required for public ingredient hazard disclosure by the Health Product Declaration (HPD)† are also included in the Pharos CML. See the “Hazard lists in Pharos” section below for the complete list.

The CML provides information describing each of the included hazard lists, how it is categorized for level of concern within the Pharos scoring system, and when the list was last updated as well as providing links directly to the website of the issuer of the list.

The list will continue to grow as the Pharos team evaluates new lists for acceptance in to the Library. Currently under consideration are more lists of asthmagens and other human health endpoints.

The Chemical Profile Display: The CML can be searched by name, synonyms, species or CAS number.‡ A search for any substance which is identified in the CML database by CAS number will return a Chemical Profile, which may contain both direct and life cycle warnings. Elements of the Chemical Profile include:

- The Direct Chemical and Compound Hazard section indicates each of the human and environmental health endpoints that one or more of the scanned authoritative hazard lists have directly associated with exposure to a specific chemical or members of its compound group (see section below on Compound Groups for more information on how these groups are populated and used in Pharos). The endpoint is color coded for the Pharos level of concern. It also indicates if the chemical is listed on any of the scanned restricted substance lists. Each listing includes:
  - Endpoint color coded by level of concern
  - Issuing organization
  - Title of the list, with a link to the Pharos description of the list
  - Abbreviation for the list, based on the GreenScreen abbreviation if any.
  - Specific statement on the list that qualifies this substance
  - GreenScreen Benchmark
  - Indication of whether the listing is required to be displayed in an HPD (in the Detailed Listing only)

There are two modes for display of the Chemical Profile Direct Hazards: Quickscreen and Detailed.
  - The Quickscreen default provides one listing per endpoint. For each endpoint a listing is displayed that has highest level of concern for that endpoint. The endpoints are displayed in order of level of hazard. If there is more than one list associating this chemical or its compound group with the particular endpoint, a link opens a box which provides a display of all of the relevant lists for that endpoint that identified this chemical or its compound group. The Quickscreen also indicates if no hazard warnings have been found for this chemical for the health and ecotoxicity endpoints that are tracked in Pharos. More information about tracked endpoints is below under “Health and ecotoxicity endpoints”.

---

* The GreenScreen for Safer Chemicals is a benchmarking system for chemical hazards that Pharos builds from in establishing its framework for assessing chemicals and products. More information about the GreenScreen is available at http://www.greenscreenchemicals.org.

† The Health Product Declaration (HPD) is a standardized format for disclosure of product content and associated health hazard developed for the building industry and managed by the Health Product Declaration Collaborative. More information on the HPD is available at http://www.hpdcollaborative.org.

‡ CAS number – a unique identifier assigned by the Chemical Abstract Service of the American Chemical Society to uniquely identify chemical elements, compounds, polymers, and other materials and mixtures. Frequently used in Material Data Safety Data Sheets (MSDSees).
The **Detailed** Hazard Listing optional version of this display displays all the listings for each endpoint, sorted by level of concern. See the section below on “Pharos health hazard levels of concern” for explanation of the color coding system. The Detailed display also indicates if this listing is required to be included in a **Health Product Declaration**. Always use the Detailed Hazard Listings for reference when using the CML to produce an HPD.

**GreenScreen Benchmark & GreenScreen List Translator:** The GreenScreen protocol establishes a four step benchmark system with Benchmark 1 indicating a chemical of High Concern and Benchmark 4 indicating an ideal chemical of Low concern. The GreenScreen List Translator provides guidance for which lists are sufficient to designate a chemical as a GreenScreen Benchmark 1 or to flag it as a Possible Benchmark 1. The Pharos CML supports the GreenScreen List Translator by providing an easy way to look up a chemical and determine at a glance if it qualifies a GreenScreen Benchmark 1 or to flag it as a Possible Benchmark 1.

Designating a chemical as a GreenScreen Benchmark 2 or higher is not possible based on lists alone because of the data gaps inherent in the list based approach. Any substance that does not get pegged at a Benchmark 1 or Possible Benchmark 1 gets tagged in the CML as a **Benchmark unspecified** if the list is included in the List Translator – this includes all the Group II Human Health Effects, even the High Hazard ones. There is no GreenScreen indication if the list is not included in the GreenScreen List Translator.

- **The Lifecycle Hazard** section of the Chemical Profile page provides a listing of some of the key hazardous chemicals used in manufacturing, their functional role category and the hazard endpoints and level of concern associated with those chemicals. There are two modes for display of the Chemical Profile Direct Hazards: **Quickscreen** and **Detailed**.
  - The **Quickscreen** version of this display provides a list of the chemicals used which may end up as residuals in a product using this substance as an ingredient and a second list of other hazardous chemicals used in manufacturing but not expected to be residuals in the final product. To develop a list of possible residuals for the **Health Product Declaration** under the HPD “Predicted by process chemistry” option, use the chemicals in the “May contain residual” list with health hazards indicated in red or purple to find the GreenScreen Benchmark 1 residual chemicals required to be disclosed.
  - The **Detailed** Full Lifecycle Map version of this display provides a breakdown of lifecycle chemicals by function and frequency of use. See the section below on “Life cycle health hazards” for explanation of the Pharos research and assessment of manufacturing chemicals.

**Use of the CML in the Pharos product assessment system:** Each product in the Pharos database has a Product Profile listing all of the known material contents for the product. For each material content ingredient, the Product Profile will include a color coded health or environmental endpoint (such as “Cancer” or “PBT”), in the Toxic Content column representing the highest concern hazard associated with that individual ingredient or expected residuals in it. There is also a color coded health or environmental endpoint in the Manufacturing Toxics column representing the highest concern hazard associated with the chemicals used in manufacturing that ingredient.

**Absence of a hazard listing does not assure the safety of a material.** Many of the approximately 80,000 chemicals in commerce have not yet been thoroughly tested and evaluated for their direct health impacts, and their absence from authoritative hazards lists does not suggest that they have been tested and found not to pose such a hazard. Listings that positively indicate low hazard for an endpoint for a material are coded in green in the CML. Only a full GreenScreen assessment, however, can actually confirm that a material has low hazard across all endpoints. The CML will begin to reflect full GreenScreen assessments soon.
Endpoints addressed in the CML - human health, ecotoxicity, physical hazard & environmental fate

Pharos addresses each of the human health and ecotoxicity endpoints used in the GreenScreen for Safer Chemicals and the US EPA’s Design for the Environment (DfE). The GreenScreen and DfE include all of the endpoints required for assessment by the Globally Harmonized System (GHS) plus several additional critical endpoints that are currently missing from the GHS. Pharos includes all of these endpoints plus several additional important environmental endpoints.

- **Group I Human**
  - **Carcinogenicity** – ability to cause or increase the risk of cancer
  - **Mutagenicity/Genotoxicity** – ability to cause or increase the rate of mutations, which are changes in genetic material in cells.
  - **Reproductive Toxicity** – ability to disrupt the male or female reproductive systems, changing sexual development, behavior or functions, decreasing fertility, or resulting in loss of the fetus during pregnancy.
  - **Developmental Toxicity incl. developmental neurotoxicity** – ability to cause harm to the developing child including birth defects, low birth weight and biological or behavioral problems that appear as the child grows.
  - **Endocrine Activity** – ability to interfere with hormone communication between cells which controls metabolism, development, growth, reproduction and behavior (the endocrine system). *Not currently included in GHS.*

- **Group II Human**
  - **Acute Mammalian Toxicity** – ability to be fatal on contact or ingestion for humans and other mammals.
  - **Systemic Toxicity/Organ Effects incl. immunotoxicity**-single exposure – ability to cause serious damage on contact or ingestion.
  - **Neurotoxicity**-single exposure – ability to cause damage to the nervous system including the brain. *Not currently included in GHS.*
  - **Eye Irritation/Corrosivity** – ability to cause irritation or serious damage to the eye.
  - **Skin Irritation/Corrosivity** – ability to irritate or serious damage to the skin.

- **Group II* Human**
  - **Systemic Toxicity/Organ Effects incl. immunotoxicity**-repeated exposure - ability to cause serious damage on contact or ingestion on long term repeated exposures.
  - **Neurotoxicity** - repeated exposure - ability to cause serious damage on contact or ingestion on long term repeated exposures.
  - **Respiratory Sensitization** – ability to result in high sensitivity such that small quantities trigger asthma, rhinitis or other allergic reactions in the respiratory system.
  - **Skin Sensitization** – ability to trigger allergic reactions on the skin.

- **Ecotoxicity**
  - **Acute Aquatic Toxicity** - a single exposure in a day may result in severe biological harm or death to fish or other aquatic organisms.
  - **Chronic Aquatic Toxicity** - long term exposure of months or years may result in irreversible harm to fish or other aquatic organisms
  - **Terrestrial Ecotoxicity** – ability to cause harm to land based plants, animals or microorganisms

- **Physical Hazard**
  - **Flammability** - easily ignited and capable of burning rapidly.
  - **Reactivity** - may spontaneously ignite or explode on its own or in contact with water.

- **Environmental fate**
  - **Persistent Bioaccumulative Toxicant (PBT)** – Does not break down readily from natural processes, accumulates in organisms concentrating as it moves up the food chain, and is harmful in small quantities. 
    Pharos does not currently include any listings which address Persistence or Bioaccumulation individually. *Not currently included in GHS.*
  - **Global Warming** – ability to absorb thermal radiation, increasing the temperature of the atmosphere and contributing to climate change. *Not currently included in GreenScreen or GHS.*
  - **Ozone Depletion** – ability to contribute to chemical reactions that destroy ozone in the earth’s upper atmosphere. *Not currently included in GreenScreen or GHS.*
Hazard lists included in the CML

As of the publication date of this document, there were over 34,000 chemical, polymer and other material substances in the library. Over 25,000 of them are associated with at least one hazard warning. The following authoritative chemical hazard lists are currently scanned:

[1] Lists assessed by GreenScreen as Benchmark 1
[2] Additional lists assessed by GreenScreen
[3] Lists which are not assessed by GreenScreen

All substances on each of these authoritative lists are included in the Pharos CML if a CAS number was provided by the list issuer. When no CAS number was provided, Pharos staff has exercised professional judgment to associate a CAS number where possible. Poorly defined substances with no CAS number association are not included in the CML at this time.

Some of the lists reference compound groups, such as lead based compounds, in addition or instead of identifying specific chemicals by CAS number. HBN staff is in the process of populating compound groups to associate more of these related chemicals with these warnings. This is an ongoing process. See the section below on Compound Groups for more information. Pharos staff updates the listings from the original issuer source on a varying base dependent on the frequency of changes by the issuer.

Information describing each list, contact information for the issuer and its update status is available at [http://www.pharosproject.net/material_list/showall](http://www.pharosproject.net/material_list/showall)
Hazard Levels & color coded Priority Levels & the GreenScreen

There is currently no single, comprehensive governmental list or database that assesses and rates all chemicals across all chemical hazards. The Pharos CML begins to address this problem by combining many single endpoint lists into one combined database that provides a view across endpoints. The CML then supports users in establishing priorities for substitution and identifying inherently safer substitutes through a two part ranking system based largely on the protocol of the GreenScreen for Safer Chemicals.

The first step of this ranking process starts is to characterize the **Hazard level** of a chemical for a single health endpoint – the potential of the chemical to trigger the human health problem, such as cancer or asthma, an ecotoxicity problem or an environmental fate such as persistence or bioaccumulation. Hazard is ranked on a five step scale from Very High to Very Low.

The second step in the ranking process is to translate the hazard level into a **Priority level** indicating the relative urgency to avoid use of this chemical and substitute for an inherently safer one. Chemicals which tend to cause more long term irreversible damage either because they are persistent and/or bioaccumulative or because they are associated with chronic systemic problems such as cancer, mutagenicity, reproductive and developmental toxicity and endocrine activity are prioritized highest. Priority is ranked on a five step color coded scale from Urgent (purple) to Low (green).

The Pharos color coded categorization is based on hazard assessment. The Pharos hazard color code does not represent a characterization of level of exposure or a risk assessment. Rather this categorization reflects current trends in chemical *hazard* management policy work. It is informed by collaborative work that HBN has engaged in for over ten years with Clean Production Action (CPA), members of Health Care Without Harm (HCWH) and the Business–NGO Working Group on chemical hazard analysis. It is specifically informed by the GreenScreen for Safer Chemicals, which uses benchmarks to rank the safety of chemicals and encourage progress toward safer alternative.

**Hazard Level (High to Low)**

- Very High Hazard
- High Hazard
- Moderate Hazard
- Low Hazard
- Very Low Hazard
- Potential Concern

Pharos assigns a level of hazard for a substance relative to an endpoint based on its potency and on scientific certainty. For most of the endpoints in Pharos, these levels are defined by the GreenScreen protocol which in turn is largely aligned with the US EPA Design for the Environment program levels. In these schemes, some endpoints are only ranked on three or four levels of the Very High-High-Medium-Low-Very Low scale. The GreenScreen List Translator assigns hazard levels to each of the lists used in the GreenScreen. Pharos uses the List Translator hazard levels for all shared lists. Where the GreenScreen indicates a hazard range instead of a single hazard level but suggests a single level for benchmarking, Pharos generally uses the GreenScreen suggested benchmark level. Where the range is too large for the GreenScreen to establish a benchmarking level and is left unspecified, Pharos generally tags the listing with “Potential Concern” but establishes levels for some lists by

---

2. Cancer, mutagenicity, reproductive toxicity and endocrine disruption stop at High hazard level and only PBT, ODP & GWP have a Very Low hazard level
3. See GreenScreen List Translator for GreenScreen associations of lists and hazards with hazard levels and benchmarks. Pharos is currently using the GreenScreenTM v1.2 List Translator available at [http://www.greenscreenchemicals.org](http://www.greenscreenchemicals.org)
expert judgment*. The GreenScreen generally does not establish benchmarking hazard levels for hazard lists which are based upon multiple endpoints (such as PBT lists). Pharos uses staff expert judgment to establish the hazard level for these and for lists not evaluated in the GreenScreen List Translator.

**Priority level (color codes)**

<table>
<thead>
<tr>
<th>Color</th>
<th>Description</th>

<tr>
<td>Green</td>
<td>Low Concern for this endpoint</td>
</tr>
</tbody>
</table>

Pharos uses a color coded ranking system to prioritize between similar hazard levels for multiple health endpoints. This system provides guidance for how to prioritize chemicals of concern for avoidance and substitution.

Pharos bases its rankings on the GreenScreen for Safer Chemicals protocol that rates toxicants that are persistent and bioaccumulative and/or have a high hazard of certain chronic diseases that tend to do irreversible damage (the Group I Human health endpoints including cancer, mutagenicity, reproductive and developmental toxicity and endocrine activity) as a higher concern than chemicals that break down rapidly or are related to other more reversible human health problems. In Pharos, The PBTs rank highest. The result is that:

- A high hazard PBT (persistent bioaccumulative toxicant) is rated at the highest priority level – a **purple** Urgent Concern.
- A high hazard carcinogen will be rated at the next highest priority level - a **red** Very High Concern.
- A high hazard respiratory sensitizer will be rated at the next highest priority level - an **orange** High Concern.
- A high hazard skin irritant will be rated at the second lowest priority level – a **yellow** Moderate Concern

The following chart indicates how very low to very high hazard levels for endpoints are prioritized into levels of concern for substitution. “Potential concern” is discussed later in this document.

PBT = Persistent Bioaccumulative toxicant  
Ozone & GW = Ozone depletion & global warming
CMR+E = GreenScreen Group I Human: Cancer, Mutagenicity / Genotoxicity, Reproductive toxicity, Developmental toxicity, Endocrine activity
Single exposure = GreenScreen Group II Human: Acute Mammalian Toxicity, Systemic Toxicity/Organ Effects-Single Exposure, Neurotoxicity-Single Exposure, Eye Irritation and Skin Irritation
Repeated Exposure = GreenScreen Group II* Human: Systemic Toxicity/Organ Effects-Repeated Exposure (including Immune System Effects), Neurotoxicity-Repeated Exposure, Respiratory Sensitization, Skin Sensitization
Physical Hazard = Flammability & Reactivity
Ecotoxicity = Acute & chronic toxicity

* For many of the listings which do not rate GreenScreen Benchmark 1 (i.e., Possible Benchmark 1 and Benchmark Unspecified) the GreenScreen provides a range instead of an absolute hazard level. Refer to the GreenScreen List Translator to confirm if the Hazard level is an absolute or a range. In certain of the range cases, such as Asthmagens - a high priority for many Pharos users - Pharos may take the precautionary step of benchmarking the listing at the higher of the two in the range instead of the GreenScreen norm of the lower. Also where the range is Moderate or Low, the Pharos may exercise judgment to categorize it at Moderate to indicate some remaining concern.
In the following sections, each Priority level is described in detail to outline which health endpoints and hazard levels are included in that Priority level.

**Purple** 
**Urgent Concern to avoid** – Material of urgent concern due to combinations of known high persistence, bioaccumulation and/or toxicity (PBT) or extremely high global warming or ozone depletion potential. Avoid immediately.

PBT substances in the Pharos Purple Urgent Concern level do not break down rapidly in the environment to more benign substances therefore accumulate and concentrate as they work up the food chain. These chemicals are those classified as known to be one of the following:

- Persistent, Bioaccumulative and Toxic (PBT)
- or any two of the criteria in combination:
- very Persistent and very Bioaccumulative (vPvB)
- very Persistent and Toxic (vPT, or
- very Bioaccumulative and Toxic (vBT))

The authoritative lists which Pharos uses to categorize chemicals at Pharos Purple Urgent Concern level also generally are categorized at a Benchmark 1 by the GreenScreen. Pharos differs from GreenScreen in separating PBT listed chemicals from other priority human health listed chemicals. This is because the fact that these chemicals are persistent and/or bioaccumulative means they will tend to be distributed more widely in geography and time before being broken down into more benign forms and hence have more opportunity to do harm.

**Global warming and ozone depletion** are not included in GreenScreen at this time but are rated by Pharos. Gases with very high hazard due to their potency with GWP greater than 10,000 or ODP greater than 0.2 – are categorized at the Pharos Purple Urgent Concern priority level.

**Red** 
**Very High Concern to avoid** - Material of very high concern due to its likelihood of causing priority human health effects or of its very high global warming or ozone depletion potential or its extremely high acute environmental toxicity. High priority to eliminate.

The criteria for the Pharos Red Very High Concern level are aligned with the single endpoint criteria for GreenScreen Benchmark 1: Avoid - Chemical of High Concern:  
- **Very High or High hazard** of a priority human health endpoint (GreenScreen Group I Human)

Other GreenScreen Benchmark 1 criteria address combinations of persistence and bioaccumulation with toxicity. Pharos categorizes all substances listed on authoritative PBT lists in the Pharos Purple Urgent Concern category described above. Pharos does not provide assessments by multiple endpoints at this time. As full GreenScreen assessments are published, however, substances which are assessed at a GreenScreen Benchmark 1 will be categorized at the Pharos Red Very High Concern level unless they are already categorized at the Pharos Purple Urgent Concern level by authoritative listing.

Substances are categorized at the Pharos Red Very High Concern level if they have been identified as known or likely to lead to a priority human health effect, defined as a high hazard of the GreenScreen Group I Human hazard endpoints:

- **Cancer** (carcinogenicity)
- **Gene mutation** (mutagenicity/genotoxicity)
- **Reproductive or developmental toxicity** (harms the reproductive system, interferes with reproduction or development of the fetus or young developing child. The above group of effects is sometimes referred to as “CMRs”) and
- **Endocrine activity** (interferes with hormones and other endocrine functioning)

“Known or likely potential” of the effects are typically characterized on a hazard list with any of the following terms:

- “Known” (as in “Known carcinogen”)
- "Known to be" (as in “Known to be carcinogenic”)
• “Is”
• “Probable”
• “Likely”
• “Presumed”
• “Reasonably anticipated”
• “Strong” (strength of evidence in CHE list)

Substances may also be categorized at the Pharos Red Very High Concern level if they have been identified as:
• likely PBTs, through modeling activities, such as QSAR, or screening level testing, but not yet confirmed by controlled testing, or
• having significant PBT characteristics in scientific studies, but have not yet been listed by a governmental hazard listing organization.

Global warming and ozone depletion gases of high hazard due to their potency with GWP between 1,000 and 10,000 and ozone depletion gases with ODP less than 0.2 – also are categorized at the Pharos Red Very High Concern level.

Unlike GreenScreen Benchmark 1, acute aquatic toxicants with extremely high potency (EU H-Statement M Factor of 100 or greater) are also included in the Pharos Red Very High Concern level. Note that acute aquatic toxicants can receive a GreenScreen Benchmark 1 if they are also very high persistence or very high bioaccumulation or high persistence and bioaccumulation. Pharos does not support this type of multiple factor assessment at this time.

Orange High Concern to avoid – Possible association with priority health effects or high potency for other acute or chronic human health effects or very high ecotoxicity or high global warming potential, flammability or reactivity. Next priority for substitution.

The criteria for the Pharos Orange High Concern level are aligned with the single endpoint criteria for GreenScreen Benchmark 2: Use but Search for Safer Substitutes:
• Moderate hazard of a priority human health effect (GreenScreen Group I Human) or
• Very High or High hazard of other chronic human health effects (GreenScreen Group II* Human)
• Very High or High hazard of flammability or reactivity
• Very high hazard of ecotoxicity
• Very high hazard of other acute human health effects (GreenScreen Group II Human)

Substances are categorized at the Pharos Orange High Concern level if they have been classified as suspected to possibly lead to any of the priority human health effects listed above under the Red Very High Concern level (the GreenScreen Group I Human health effects category), “Suspected association” with the priority health effects can be characterized on a hazard list with any of the following terms:
• “Possible”
• “Suggestive”
• “Suspected”
• “May cause”
• “Limited evidence’
• “Danger of”
• “Good ” (strength of evidence in CHE list)

Substances are categorized at the Pharos Orange High Concern level if their level of potency for the following acute and chronic human health effects is defined as a very high hazard of the GreenScreen Group II Human hazard endpoints:
• Acute Mammalian Toxicity
• Systemic Toxicity/Organ Effects-Single Exposure

1 QSAR which identify structural similarity between the targeted substance and other known toxicants
• Neurotoxicity-Single Exposure
• Eye Irritation and Skin Irritation.
or
a high hazard of the GreenScreen Group II* Human hazard endpoints:
• Systemic Toxicity/Organ Effects-Repeated Exposure (including Immune System Effects)
• Neurotoxicity-Repeated Exposure
• Respiratory Sensitization
• Skin Sensitization

Substances are also categorized at the Pharos Orange High Concern level if they meet GreenScreen Benchmark 2 criteria for ecotoxicity, flammability or reactivity –
a high hazard of flammability or reactivity
or
a very high hazard of ecotoxicity, including:
• Acute Aquatic Toxicity
• Chronic Aquatic Toxicity
• Ecotoxicity

Substances may also be categorized at the Pharos Orange High Concern level if they have been identified through modeling activities, such as QSAR, or screening level testing, as likely associated with a priority health concern but not yet confirmed by controlled testing, or

Global warming gases of medium hazard due to their potency with GWP between 100 and 1000 – also are categorized at the Pharos Orange High Concern level.

Other GreenScreen Benchmark 2 criteria address combinations of persistence and bioaccumulation with toxicity. Pharos does not provide assessments by multiple endpoints at this time. As full GreenScreen assessments are published, however, substances which are assessed at a GreenScreen Benchmark 2 will be categorized at the Pharos Orange High Concern level.

Pending the publication of full GreenScreen assessments of chemicals, categorization in this level of concern is determined solely by the use of authoritative lists, not by the full toxicological assessment as defined under the GreenScreen. A Pharos Orange High Concern level categorization should not be assumed to be a final assessment of the level of concern, but rather is a minimum rating of concern. Substantial gaps exist in data for most chemicals in use today. It is possible that with further study that any orange chemical may be demoted to the red or even purple level either due to its listing on an authoritative list or due to the publication of a GreenScreen assessment that identifies further hazards than authoritative listings have previously revealed.

Chemicals on lists assessed by GreenScreen at Possible GreenScreen Benchmark 1 will be categorized at least in the Pharos Orange High Concern level categorization and may move up to red or purple if they meet criteria above.

Yellow Moderate concern to avoid - Known acute health effects, known ecotoxicity, suspected other chronic (non priority) health effects, moderate global warming or very preliminary data of possible association with priority health effects. Avoid when possible.

The criteria for this category are aligned with the criteria for GreenScreen Benchmark 3: Use but Still Opportunity for Improvement. Criteria are:
• Moderate hazard of ecotoxicity
• Moderate hazard of other chronic human health effects (GreenScreen Group II or II* Human) or
• Moderate flammability or reactivity
Substances are categorized at the Pharos Yellow High Concern if their level of potency for the following acute and chronic human health effects is defined as a **high or moderate hazard** of the GreenScreen Group II Human hazard endpoints:
- Acute Mammalian Toxicity
- Systemic Toxicity/Organ Effects-Single Exposure
- Neurotoxicity-Single Exposure
- Eye Irritation and Skin Irritation

or a **moderate hazard** of the GreenScreen Group II* Human hazard endpoints:
- Systemic Toxicity/Organ Effects-Repeated Exposure (including Immune System Effects)
- Neurotoxicity-Repeated Exposure
- Respiratory Sensitization
- Skin Sensitization

This category is informed by the GreenScreen Benchmark 3: *Use but Still Opportunity for Improvement*, but is determined solely by the use of authoritative lists pending the publication of full GreenScreen assessments of chemicals, not by full toxicological assessment as required under the GreenScreen and should not be assumed to be a final assessment of concern, but rather is a minimum rating of concern. Substantial gaps exist in data for most chemicals in use today. It is possible that with further study that any yellow chemical may be demoted to the orange, red or even purple level either due to its listing on an authoritative list or due to the publication of a GreenScreen assessment that identifies further hazard then authoritative listings have previously revealed.

This category also includes substances about which sufficient concern about a potential priority health effect has been raised for them to be considered by at least one of the governmental hazard listing organizations, but the organization has not yet found adequate data to characterize the hazard. Substances in this category can be characterized on a hazard list with any of the following terms:
- “Unknown”
- “Not classifiable”

Substances are also categorized at the yellow moderate concern category if they have been listed by a governmental hazard listing organization for a priority health effect, but subsequently delisted due to a determination that evidence does not reach the threshold for listing, but which have not been clearly established to not be associated with the health effect.

If there are preliminary indications of concern for priority health endpoints but only from a small number of tests with too little data to confidently determine higher concern, such as substances on lists derived from a literature searches (like CHE) that characterize the data as:
- “Weak” or “Limited”

**Global warming** gases of medium hazard due to their potency with GWP between 10 and 100 – also are categorized at the Pharos Yellow Moderate Concern level.

---

**Green**

**Low Concern** - Material studied and found not to cause the specifically listed health impact. Not an indicator of likelihood of other health impacts unless the chemical has passed GreenScreen Benchmark 4 Prefer – Safer Chemical. Watch for other hazards.

This category identifies that the issuer of the hazard list has reviewed testing of the substance and determined that there is sufficient evidence that the substance does not cause the health impact listed. This judgment is limited to the specifically identified health effect and does not in any way imply that the substance is ‘green’ or safe in regard to other health effects. There may be other health impacts associated with this material. For example a chemical may get a green code on cancer, but a red code on reproductive toxicity.
**Exposure & Risk:** The Pharos color coding characterizes a relative hazard concern level based upon the manner in which the substance is listed on each authoritative hazard list. Presence is sufficient and is not adjusted by concentration or amount. Exposure pathways and risk assessment are not a factor. The relatively low concern color codes (yellow and green) imply no warranty of the overall safety of the substance.
Restricted Substance lists & the Blue Concern Level

Chemical hazard lists color coded as indicated in the previous section identify an authoritative scientific judgment on the relationship between a substance and one (or a specific limited set) of health endpoints. Chemical hazard lists may be regulatory or they may just be informative. An additional color is reserved, however, for indications of potential concern with a substance which cannot be pegged to a specific concern level in the above protocol. Lists of chemicals will be included here in the near future with associations due to preliminary science which has not been reviewed through the consensus bodies engaged with most of the above authoritative hazard warning lists. The blue color code, however, is currently primarily used for tagging Restricted Substance Lists (RSL). RSLs are primarily policy decisions, rather than scientific judgments, identifying substances for avoidance, monitoring or careful management.

### Blue

**Potential Concern** – A substance identified on a Restricted Substance List (RSL), generally due to multiple endpoints and/or other hazard lists or being identified as raising preliminary concerns due to emerging science. This also may be used to indicate a hazard warning on an authoritative list that has been suspended or temporarily withdrawn or to indicate a hazard warning with an ambiguous hazard level.

RSLs may reflect a policy statement by a:
- non profit organization such as Cascadia’s the LBC Red list or
- for profit company, such as Perkins + Will Architecture in their Precautionary List or
- governmental agency, such as the European Commission's Directive on the Restriction Of the use of certain Hazardous Substances (ROHS).

RSLs are often based upon a synthesis of scientific judgments, but they are generally not adding new scientific assessment about a substance’s relationship to a specific health endpoint. These RSLs receive the blue level of concern color and are not included in the Pharos scoring system, but are provided solely for informational purposes.

Some RSLs are color coded with a purple to yellow specific level of concern instead of the blue level when the listing has been assigned a specific hazard level and Benchmark in the GreenScreen.

Some RSLs are color coded green when they are positive lists that exempt a substance from regulation or management due to an inherently low hazard in one or more endpoints or characteristics. This should not be interpreted as necessarily meaning that the substance has been cleared of concern at all endpoints unless a full GreenScreen has been undertaken. Watch for other flags.

The blue color coded concern level is not displayed in the Material Contents ingredient list of a product profile unless no other colors trump it in the display.

RSL lists currently scanned include:

1. **EC EC - REACH Exemptions** European Commission, Commission Regulation (EC) No 987/2008 Annex I & 2 Exemptions from the Obligation to Register in accordance with REACH article 2(7)a
2. **EC – ROHS** European Commission, Directive on the Restriction Of the use of certain Hazardous Substances in electrical and electronic equipment ANNEX II
3. **Environment Canada - Toxic Substances List - Sched 1 (CEPA)** Environment Canada & Health Canada, Canadian Environmental Protection Act (CEPA) - Environmental Registry - Toxic Substances List (Schedule 1)
4. **Environment Canada - Virtual Elimination List (CEPA)** Environment Canada & Health Canada, Canadian Environmental Protection Act (CEPA) - Environmental Registry - Virtual Elimination List
5. **German FEA - Substances Hazardous to Waters (VwVwS)** German Federal Environment Agency, Administrative Regulation on the Classification of Substances hazardous to waters into Water Hazard Classes (Verwaltungsvorschrift wassergefährdende Stoffe)
6. **Hazardous 100 (SCHF)** Safer Chemicals, Healthy Families, Hazardous 100+ List of Chemicals of High Concern
7. **HBN - Priority Asthmagens** Healthy Building Network, HBN Priority Building Material Asthmagens List
9. P+W - Precautionary List Perkins+Will, Precautionary List
11. US EPA - Exempt VOCs US Environmental Protection Agency, VOCs which have been determined to have negligible photochemical reactivity and so are exempt
13. US OSHA – Carcinogens US Department of Labor, TRI Carcinogens
14. USGBC - LEED Credits (LEED) US Green Building Council, LEED Credits: Chemical Avoidance in Building Materials
Compound groups

Many materials are identified on chemical hazard lists individually and referenced by their specific CAS Registry Number (often called just CAS number). Currently the CML provides complete listings of all chemicals listed directly by CAS number in the hazard list. In other cases, however a hazard list will identify a group of structurally similar compounds (such as lead compounds) as all having the same hazard. The Pharos staff is in the process of establishing compound groups of these similar compounds and associating warnings from the hazard lists with them as well. Building these groups will be an ongoing process.

Hazard warnings are tagged to indicate if they are applied to a substance because of its membership in a compound group. The Compound Group box of the Chemical Profile page indicates the name of any compound group of which this material is a member.
Life cycle health hazards

The hazards from substances involve much more than the direct health hazards of exposure to the substance. Different chemicals are used, created and emitted at different stages of extraction, harvesting and manufacturing of a material. Some substances will degrade over time, emitting different chemicals and a host of new chemicals may be formed if the product burns accidentally in use or in an incinerator or landfill at the end of life. These chemicals may pose occupational safety hazards to those who work in the mines, agricultural fields and factories, incinerators or landfills along the life cycle or in the nearby communities.

HBN has begun to compile information on the chemicals involved in the life cycle of key materials used in products in the Pharos database. For each ingredient of a Pharos listed product, Pharos staff conducts a preliminary literature review of life cycle hazard associations to establish a representative assessment of the entire life cycle of the material. More in-depth research is conducted on select common ingredients.

Primary resources for this research are:

- the NREL US Life-Cycle Inventory Database at http://www.nrel.gov/lci/database/default.asp

and a variety of other governmental and non governmental information sources. Each chemical record is a work-in-progress and does not necessarily represent all chemicals that may be used, created or emitted in the life cycle of a material. We welcome submissions and suggestions to improve our life cycle hazard data.

The life cycle information listed here is for generic versions of the material. In cases where there are multiple chemical synthesis pathways for manufacturing the material, the record may include information on multiple pathways and will indicate which chemicals are integral and hence used all the time and which ones represent options and will only be used in some instances. Manufacturers will have the option to improve scoring of a product by providing product specific life cycle information when they can document that their supply chain does not use certain chemicals of concern.

The CML expresses this information in the Life Cycle section of the Chemical Profile. Substances are identified for hazard by hazard lists as in the Direct Health Hazards, with the same Pharos health hazard prioritization and color coding.

Chemical involvement in the life cycle is categorized broadly by:

- Use in manufacture
- Exposure in use
- Exposure in degradation
- Exposure in combustion

**Use in manufacture:** Manufacture can include any step from cradle to gate – that is from the initial extraction of the feedstock from the earth at a mine or well or from growing plants (cradle) through to the end of manufacture of the final material (factory gate). Chemicals are categorized as:

- **Feedstock:** Bulk raw material constituting the principal input for an industrial process.
- **Monomer:** Molecule that bonds chemically with other molecules to form a polymer, such as vinyl chloride monomers that are linked to form polyvinyl chloride or glucose monomers that are linked to form such polymers as starch and cellulose.
- **Catalyst:** Substance, usually used in small amounts relative to the reactants, that modifies and increases the rate of a reaction without being consumed.
- **Additive – non-reactive:** Chemical that is added to provide specific characteristics to the final compounds and remains in the form in which it was added, such as phthalate plasticizers or paraffin flame retardants.
- **Additive - reactive:** Chemical that is added to a compound and reacts with another additive to produce a different compound.
- **Intermediate:** Chemical that is formed from a preceding process that is further reacted and generally consumed in subsequent processes.
- **Byproduct**: Substance generated from production that is not useful to production of the target material and that is used in other processes or managed as waste or released into the work environment or released to the outdoor environment.
- **Contaminant**: Unintentional and unwanted substance that comes mixed with the target material. May originate from contaminant components to the original feedstock or as a byproduct of the chemical processes that are used to create the material.
- **Unknown role**

All of these chemicals create potential exposure issues for the workers and to neighboring communities (if emitted). The feedstocks, intermediates, reactive additives and byproducts generally do not end up in products so are not an exposure concern for users. Monomers, catalysts and contaminants sometimes end up in products, usually in trace amounts. Non reactive additives are frequently intended to end up in products in amounts that range from trace to very large percentages. Pharos differentiates in product scoring between additives that are reactive and transformed in the manufacturing process into a new substance and those that are non reactive and remain in their original form in the final product.

A variety of a chemical is categorized for each of the chemicals:

- **Frequency role in manufacturing**: a substance’s use or creation in the manufacturing process is characterized by how common it is:
  - **Integral**: A substance (such as a monomer) that is necessarily inherent to the manufacture of this material and without which it would be a different material or for which no alternatives have been demonstrated.
  - **Frequent**: A substance that is commonly used - associated with at least one third of the manufacturing process references researched - but is a design option. Alternate production methods do not involve this substance.
  - **Occasional/Rare**: A substance that is only infrequently used – found in less than one third of the manufacturing processes references researched.
  - **Unknown**: No known use in manufacturing or unclear.

- **Residual exposure in use**: The substance can be emitted from products with this material in their contents during use – hence is a potential exposure hazard for users. Options are:
  - **Yes**: Testing finds consistently that such products do emit the substance
  - **Possible**: Theory indicated or testing finds that occasionally such products do emit or materials of similar structure (such as other members of a compound group) have been shown to emit this substance
  - **No**: Not found in any use testing to date and not known from similar products.
  - **Unknown**: No known evaluation of use exposure or unclear.
Hazards that do not apply to the use phase

Pharos uses these warnings for scoring in the User Toxicity, Toxic Content and Manufacturing Toxicity sections. See the online Framework descriptions in the Pharos tool for detail about how these hazards are scored.

Some hazard list warnings are not applicable to the health of building occupants and so are not included in the scoring for the Toxic Content, only in the Manufacturing Toxicity category. These are:
- Aquatic toxicity
- Ozone depletion
- Global warming
- Occupational specific health hazards

Occupational specific hazards refers to health hazard assessments that are specific to a hazard from a particular form of the substance that generally only occurs in the conditions of the manufacture of the product. Sometimes the warning explicitly identifies this hazard as only associated with manufacture and not being applicable to the use phase of a product containing the substance. An example of this is the hazard warnings for airborne crystalline silica particles of respirable size in the Prop 65 and IARC lists. These materials are likely only to be in this form (airborne and respirable size) during manufacture, not in use in final form in the building.

As Pharos move into more exterior product, such as the roof membranes already published, this toxic content exclusion will be changed to emphasize those endpoints that could be particularly hazardous for the environment surrounding the building.
Endangered Species

Endangered species identification and lists

Use of biobased materials whether from agricultural plants or from trees is appealing due to their renewable nature. Overharvesting, plantation farming, chemical use and other problems, however, threaten many species of trees with extinction as well as threatening entire forest habitats and the animals and humans that depend upon them.

A variety of state, national and international governmental bodies and non governmental organizations (NGOs) maintain endangered species identification lists. These are lists of plant and animal species for which an authoritative body has reviewed assessments of the health and distribution of the species and pressures on their native environment to identify species that are threatened with extinction and then categorized the species to identify the level of threat.

Pharos screens forestry products and other biobased materials against these authoritative lists to identify trees and other timber plant species that are directly endangered or are frequently harvested from threatened forest habitats. Some warnings are for a specific species and others are for groups of species.

Wood is often very ambiguously named. Scientific names (genus and species, where species are names for related plants within a larger species group) should provide a consistent way of identifying a specific type of plant, but botanists frequently do not agree on the scientific naming of a plant. Trade names can be even more ambiguous. The same common trade name may refer to many different related species of wood and sometimes even totally unrelated species from a different genus. The Pharos staff is working to identify the different synonyms and scientific names that may apply to commercially available woods and cross-indexing them in the CML tool.

The CML may be searched by common trade names and by scientific names (genus & species). Pharos then searches based upon the variations on the common name and different applicable genus and species combinations to provide a range of possible warnings that may apply to the named wood. These warnings are color coded to indicate the relative level of concern in Pharos of that warning. See the section below on “Pharos species warning levels of concern” for explanation of the color coding system.

Any wood species with an orange warning or higher should be avoided entirely unless its harvest was certified by a robust independent sustainable forestry certification system such as the FSC or better. Even yellow coded species should be used with caution and avoided when possible due to possible threats to endangered species and destruction of critical forest habitats.

Absence of a warning listing does not assure that a species is free of threats.

Wood naming is ambiguous and subject to confusion. Synonyms are prolific for many species. Many species have not yet been adequately assessed and building of this database is an ongoing process. Nonetheless for those wood needs for which supplies of sustainably harvested timber certified by FSC or better, this Library is rapidly becoming the most comprehensive index of threat status for species of woods used in construction.
Species list status

As of the publication of this document, there were over 1000 species of trees and other building related plants in the biobased portion of the Library with hazard warnings on the majority of them. The following lists are scanned:

1. **IUCN Red List of Threatened Species** - International Union for Conservation of Nature and Natural Resources, Species Survival Commission
2. **UNEP WCMC CITES-listed Trees** - United Nations Environment Programme - World Conservation Monitoring Centre (WCMC)
3. **USDA Threatened & Endangered Trees Database** – US Department of Agriculture, Natural Resources Conservation Service
5. **FOE Good Wood Guide** – Friends of the Earth

Information describing each list, contact information for the issuer and its update status is available at [http://www.pharosproject.net/hazard](http://www.pharosproject.net/hazard)
Pharos species warning levels of concern

Species warnings are color coded to indicate the Pharos system's prioritization of concern based upon the degree of the threat to the species. One of the most widely accepted criteria sets for rating the threat to endangered species is the IUCN Red List Categories and Criteria prepared by the Species Survival Commission of the IUCN (International Union for Conservation of Nature and Natural Resources). Pharos structures its prioritization of the relative significance of threats based upon the IUCN categories.

- **Purple**: Extinct (EX) or Critically Endangered (CE) - species is extinct or facing an extremely high risk of extinction. Species that have been listed as extirpated in one or more US states (that is are locally extant but may still be extant in other locations) are also included in this category.

- **Red**: Endangered (EN) - species is facing a very high risk of extinction. Pharos also places most endangered species warnings from organizations that do not use the IUCN classification system into this category. This also includes species that are endangered in one of more states, even if they may be abundant in other locations.

- **Orange**: Vulnerable (VU) - species is facing a high risk of extinction. Frequently referred to as Threatened.

- **Yellow**: Near Threatened (NT) - species is not yet considered vulnerable or endangered, but is close to qualifying for or is likely to qualify for a threatened category in the near future. Species not yet evaluated (NE) are included here. Data deficient species (DD) are also included in this category where more information is required and the possibility that future research will show that threatened classification is appropriate.

- **Green**: Least Concern (LC) – species is still widespread and abundant.

* [http://www.iucnredlist.org/about/red-list-overview#redlist_criteria](http://www.iucnredlist.org/about/red-list-overview#redlist_criteria)
